Response to the peer review by Group I

Group H, Vélib' project. Review of our 29.09 submission; changes made for 03.11.2026.

Thank you to Group I: running our code on the raw files rather than only reading our documents is what found the main problem below, before it was built into the dataset.

#	Point raised	What we did	Where
1	**`last_reported` is not the time of the counts** (main recommendation)	Confirmed on our data: 90.5% of count changes happen while `last_reported` is unchanged; it renews about hourly, day and night. Dropped the deduplication on it, keep every capture, renamed `lag_min` to `lr_age_min`. Ran the test you proposed: at 60 min, or with our old plan, only about 1 episode in 6 is still counted, and the share of time without a bike drops from 6.67% to 5.82% with the old plan.	`sampling_test.py`, quality doc, "The main correction"
2	Question: "300 m from the user" vs station to station	The question now says station to station, and why	README, quality doc, first section
3	Usable for whom: renting vs returning	Two separate sides everywhere: `can_rent`, `can_return`, episodes per side	`clean.py`, `episodes.py`, dictionary
4	"Everywhere": unit of comparison	Communes, summarised as Paris vs the rest of the network	Question
5	Source of the 300 m	velib-metropole.fr/communes/paris (Paris only; our check shows it does not hold in the suburbs)	README
6	Population is not users	Used as context (stations per resident, density), never as people affected	README
7	Station count not constant; match each day with that day's list	Each day is joined with its own station list. New flags `temporary` (listed under half the days) and `event_station` (100+ docks: Concorde and Invalides, which presence alone would miss)	`clean.py` step 2
8	Check file content, not only the HTTP code (21.09 22:50)	`collect.sh` v2 checks every file before archiving (ok / partial / bad, bad files quarantined). `validate.py` checks every past file: it finds exactly that capture, kept because the counts are present	`collect.sh`, `validate.py`
9	Compare VM1 and VM2	Comparison script ready (captures per day per machine, slots caught by one only, same values at the same slot). Run on the full archives for the final report	`compare_vms.py`
10	Both VMs in the same region	Kept in Denmark East and stated as a limit: a regional outage would hit both. It would show as a gap in both logs; none up to the 29.09 snapshot	README, limits

Two limits of the reading that Group I flagged themselves, and that we keep: we can only describe how `last_reported` behaves, not why (only the operator could say), and the counts are renewed at least every 5 minutes, which does not prove they are instantaneous.
